Since each exterior angle equals the angles formed by the segments drawn from the center of the regular pentagon, the minimum degrees necessary to carry a regular polygon onto itself are equal to the measure of an exterior angle of the regular polygon.

The given line \(h\), \(2x + y = 1\), does not pass through the center of dilation, the origin, because the \(y\)-intercept is at \((0, 1)\). The slope of the dilated line, \(m\), will remain the same as the slope of line \(h\), 2. All points on line \(h\), such as \((0, 1)\), the \(y\)-intercept, are dilated by a scale factor of 4; therefore, the \(y\)-intercept of the dilated line is \((0, 4)\) because the center of dilation is the origin, resulting in the dilated line represented by the equation \(y = -2x + 4\).

Triangle $X'Y'Z'$ is the image of $\triangle XYZ$ after a rotation about point $Z$ such that $\overrightarrow{ZX}$ coincides with $\overrightarrow{ZU}$. Since rotations preserve angle measure, $\overrightarrow{ZY}$ coincides with $\overrightarrow{ZV}$, and corresponding angles $X$ and $Y$, after the rotation, remain congruent, so $\overrightarrow{XY} \parallel \overrightarrow{UV}$. The line $y = 2x - 4$ does not pass through the center of dilation, so the dilated line will be distinct from $y = 2x - 4$. Since a dilation preserves parallelism, the line $y = 2x - 4$ and its image will be parallel, with slopes of 2. To obtain the $y$-intercept of the dilated line, the scale factor of the dilation, $\frac{3}{2}$, can be applied to the $y$-intercept, $(0,4)$.
