The line $y = 2x - 4$ does not pass through the center of dilation, so the dilated line will be distinct from $y = 2x - 4$. Since a dilation preserves parallelism, the line $y = 2x - 4$ and its image will be parallel, with slopes of 2. To obtain the $y$-intercept of the dilated line, the scale factor of the dilation, $\frac{3}{2}$, can be applied to the $y$-intercept, $(0,-4)$. Therefore, $\left(0, \frac{3}{2}, -4, \frac{3}{2}\right) \rightarrow (0,-6)$. So the equation of the dilated line is $y = 2x - 6$.

It is given that point \( D \) is the image of point \( A \) after a reflection in line \( CH \). It is given that \( CH \) is the perpendicular bisector of \( BCE \) at point \( C \). Since a bisector divides a segment into two congruent segments at its midpoint, \( BC \cong EC \). Point \( E \) is the image of point \( B \) after a reflection over the line \( CH \), since points \( B \) and \( E \) are equidistant from point \( C \) and it is given that \( CH \) is perpendicular to \( BE \). Point \( C \) is on \( CH \), and therefore, point \( C \) maps to itself after the reflection over \( CH \).
