A parabola with a focus of (0,4) and a directrix of \( y = 2 \) is sketched as follows: 

By inspection, it is determined that the vertex of the parabola is (0,3). It is also evident that the distance, \( p \), between the vertex and the focus is 1. It is possible to use the formula \( (x - h)^2 = 4p(y - k) \) to derive the equation of the parabola as follows: 

\[
(x - 0)^2 = 4(1)(y - 3)
\]

\[
x^2 = 4y - 12
\]

\[
x^2 + 12 = 4y
\]

\[
\frac{x^2}{4} + 3 = y
\]

or A point \((x,y)\) on the parabola must be the same distance from the focus as it is from the directrix. For any such point \((x,y)\), the distance to the focus is \( \sqrt{(x - 0)^2 + (y - 4)^2} \) and the distance to the directrix is \( y - 2 \). Setting this equal leads to:

\[
x^2 + y^2 - 8y + 16 = y^2 - 4y + 4
\]

\[
x^2 + 16 = 4y + 4
\]

\[
\frac{x^2}{4} + 3 = y
\]

This scenario can be modeled with a Venn Diagram:

Since 

\[
P(S \cup I) = 0.2, P(S \cap I) = 0.8
\]

Then, 

\[
P(S \cap I) = P(S) + P(I) - P(S \cup I)
\]

If \( S \) and \( I \) are independent, then the

\[
= 0.5 + 0.7 - 0.8
\]

= 0.4
\]

Product Rule must be satisfied. However, \((0.5)(0.7) \neq 0.4\). Therefore, salary and insurance have not been treated independently.

The mean difference between the students’ final grades in group 1 and group 2 is –3.64. This value indicates that students who met with a tutor had a mean final grade of 3.64 points less than students who used an on-line subscription. One can infer whether this difference is due to the differences in intervention or due to which students were assigned to each group by using a simulation to rerandomize the students’ final grades many (500) times. If the observed difference –3.64 is the result of the assignment of students to groups alone, then a difference of –3.64 or less should be observed fairly regularly in the simulation output. However, a difference of –3 or less occurs in only about 2% of the rerandomizations. Therefore, it is quite unlikely that the assignment to groups alone accounts for the difference; rather, it is likely that the difference between the interventions themselves accounts for the difference between the two groups’ mean final grades.

Yes. The margin of error from this simulation indicates that 95% of the observations fall within \( \pm 0.12 \) of the simulated proportion, 0.25. The margin of error can be estimated by multiplying the standard deviation, shown to be 0.06 in the dotplot, by 2, or applying the estimated standard error formula, \( \sqrt{\frac{p(1-p)}{n}} \) or \( \sqrt{\frac{(0.25)(0.75)}{50}} \), and multiplying by 2. The interval 0.25 \( \pm 0.12 \) includes plausible values for the true proportion of people who prefer Stephen’s new product. The company has evidence that the population proportion could be at least 25%. As seen in the dotplot, it can be expected to obtain a sample proportion of 0.18 (9 out of 50) or less several times, even when the population proportion is 0.25, due to sampling variability. Given this information, the results of the survey do not provide enough evidence to suggest that the true proportion is not at least 0.25, so the development of the product should continue at this time.
