Fifty cola drinkers are randomly selected to take a blind taste-test of products \(A\), \(B\), and the new product. 37 Drugs break down in the human body at different rates and therefore must be prescribed by doctors carefully to prevent complications, such as overdosing. The breakdown of a drug is represented by the function

\[ N(t) = N_0(e^{-rt}) \]

where \( N(t) \) is the amount left in the body, \( N_0 \) is the initial dosage, \( r \) is the decay rate, and \( t \) is time in hours. Patient \( A \), \( A(t) \), is given 800 milligrams of a drug with a decay rate of 0.347. Patient \( B \), \( B(t) \), is given 400 milligrams of another drug with a decay rate of 0.231. Write two functions, \( A(t) \) and \( B(t) \), to represent the breakdown of the respective drug given to each patient. Graph each function on the set of axes below.

To the nearest hour, \( t \), when does the amount of the given drug remaining in patient \( B \) begin to exceed the amount of the given drug remaining in patient \( A \)? The doctor will allow patient \( A \) to take another 800 milligram dose of the drug once only 15% of the original dose is left in the body. Determine, to the nearest tenth of an hour, how long patient \( A \) will have to wait to take another 800 milligram dose of the drug.

The zeros of the polynomial are at \(-b\), and \(c\). The sketch of a polynomial of degree 3 with a negative leading coefficient should have end behavior showing as \(x\) goes to negative infinity, \(f(x)\) goes to positive infinity. The multiplicities of the roots are correctly represented in the graph.

A parabola with a focus of \((0,4)\) and a directrix of \(y = 2\) is sketched as follows: By inspection, it is determined that the vertex of the parabola is \((0,3)\). It is also evident that the distance, \(p\), between the vertex and the focus is 1. It is possible to use the formula \((x-h)^2 = 4p(y-k)\) to derive the equation of the parabola as follows: 
\[
(x - 0)^2 = 4(1)(y - 3)
\]
\[
x^2 = 4y - 12
\]
\[
x^2 + 12 = 4y
\]
\[
\frac{x^2}{4} + 3 = y
\]

or A point \((x,y)\) on the parabola must be the same distance from the focus as it is from the directrix. For any such point \((x,y)\), the distance to the focus is \(\sqrt{(x - 0)^2 + (y - 4)^2}\) and the distance to the directrix is \(y - 2\). Setting this equal leads to: 
\[
x^2 + y^2 - 8y + 16 = y^2 - 4y + 4
\]
\[
x^2 + 16 = 4y + 4

Yes. The margin of error from this simulation indicates that 95% of the observations fall within ± 0.12 of the simulated proportion, 0.25. The margin of error can be estimated by multiplying the standard deviation, shown to be 0.06 in the dotplot, by 2, or applying the estimated standard error formula, \[\sqrt{\frac{p(1-p)}{n}}\] or \[\sqrt{\frac{(0.25)(0.75)}{50}}\]

and multiplying by 2. The interval 0.25 ± 0.12 includes plausible values for the true proportion of people who prefer Stephen’s new product. The company has evidence that the population proportion could be at least 25%. As seen in the dotplot, it can be expected to obtain a sample proportion of 0.18 (9 out of 50) or less several times, even when the population proportion is 0.25, due to sampling variability. Given this information, the results of the survey do not provide enough evidence to suggest that the true proportion is not at least 0.25, so the development of the product should continue at this time.

The amplitude, 12, can be interpreted from the situation, since the water level has a minimum of \(-12\) and a maximum of 12. The value of \( A \) is \(-12\) since at 8:30 it is low tide. The period of the function is 13 hours, and is expressed in the function through the parameter \( B \). By experimentation with technology or using the relation \( P = \frac{2\pi}{B} \) (where \( P \) is the period), it is determined that \( B = \frac{2\pi}{13} \).

\[ f(t) = -12 \cos \left( \frac{2\pi}{13} t \right) \]

In order to answer the question about when to fish, the student must interpret the function and determine which choice, 7:30 pm or 10:30 pm, is on an increasing interval. Since the function is increasing from \( t = 13 \) to \( t = 19.5 \) (which corresponds to 9:30 pm to 4:00 am), 10:30 is the appropriate choice.

The mean difference between the students’ final grades in group 1 and group 2 is –3.64. This value indicates that students who met with a tutor had a mean final grade of 3.64 points less than students who used an on-line subscription. One can infer whether this difference is due to the differences in intervention or due to which students were assigned to each group by using a simulation to rerandomize the students’ final grades many (500) times. If the observed difference –3.64 is the result of the assignment of students to groups alone, then a difference of –3.64 or less should be observed fairly regularly in the simulation output. However, a difference of –3 or less occurs in only about 2% of the rerandomizations. Therefore, it is quite unlikely that the assignment to groups alone accounts for the difference; rather, it is likely that the difference between the interventions themselves accounts for the difference between the two groups’ mean final grades.
